

ARPES study of transition metal substitutions in Sr_2IrO_4

Véronique Brouet, Alex Louat, Paul Foulquier
Laboratoire de Physique des Solides d'Orsay

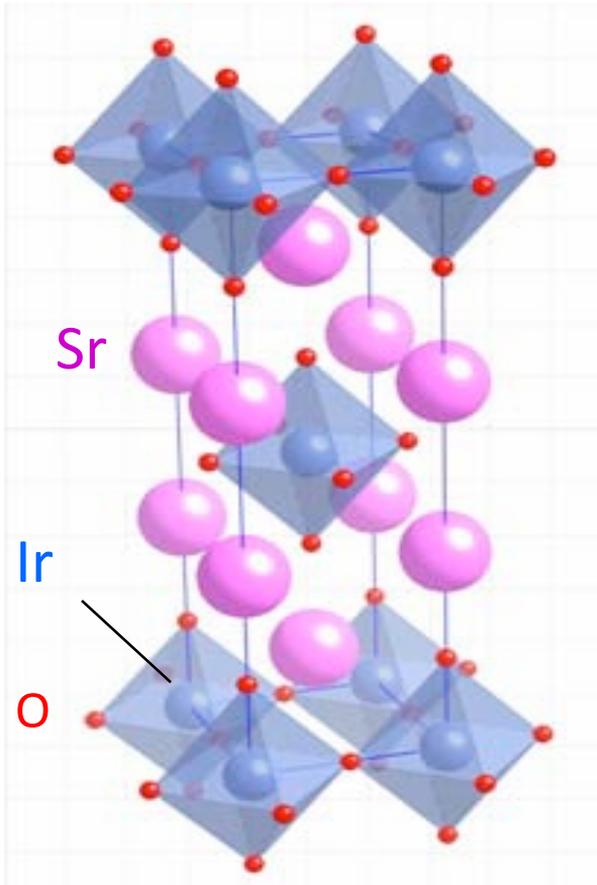

ARPES experiments : SOLEIL synchrotron, CASSIOPEE beamline

Patrick Le Fèvre, François Bertran, Julien Rault

Sample synthesis

LPS and Dorothée Colson, Anne Forget : SPEC, CEA-Saclay, France

Outline

Sr_2IrO_4
(simplified structure)

- New type of Mott insulator :
=> Spin-orbit Mott insulator
- New type of correlated metals ?
=> Sr/La substitutions
=> Ir/transition metal substitutions

obtained : hole doping

Rh : expected : isovalent
obtained : hole doping

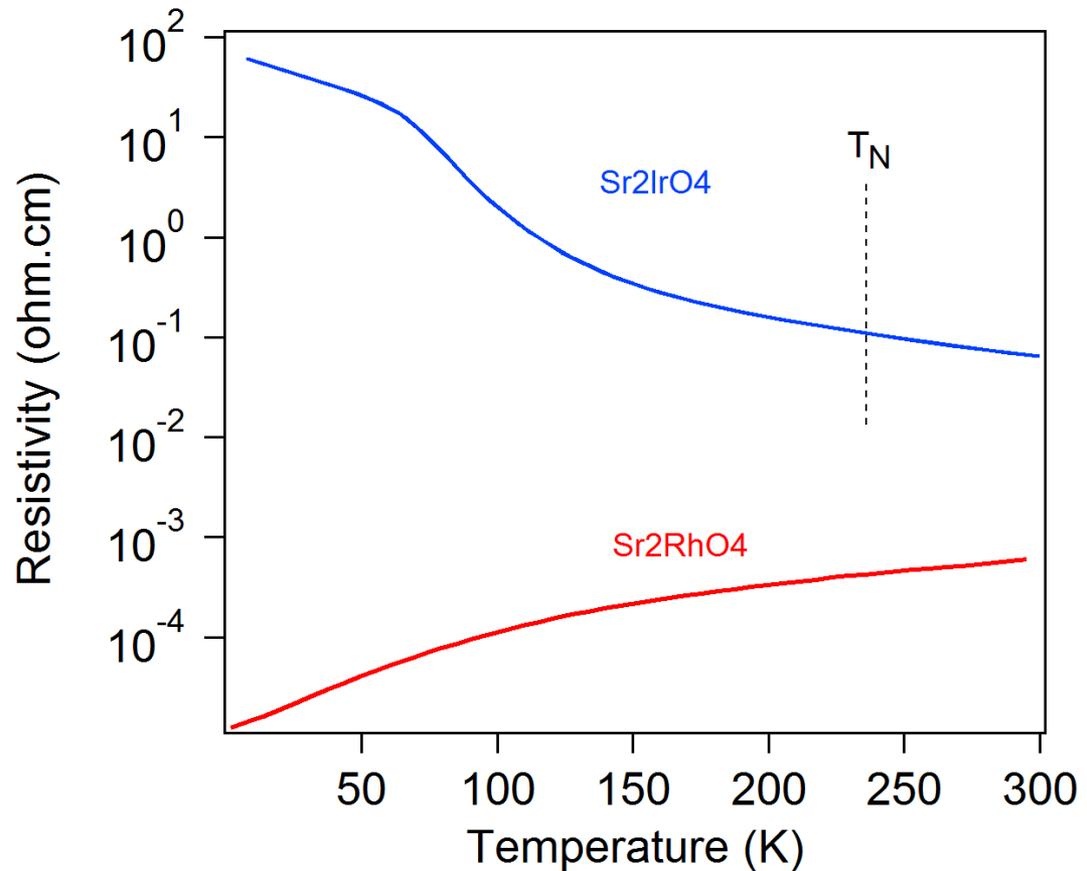

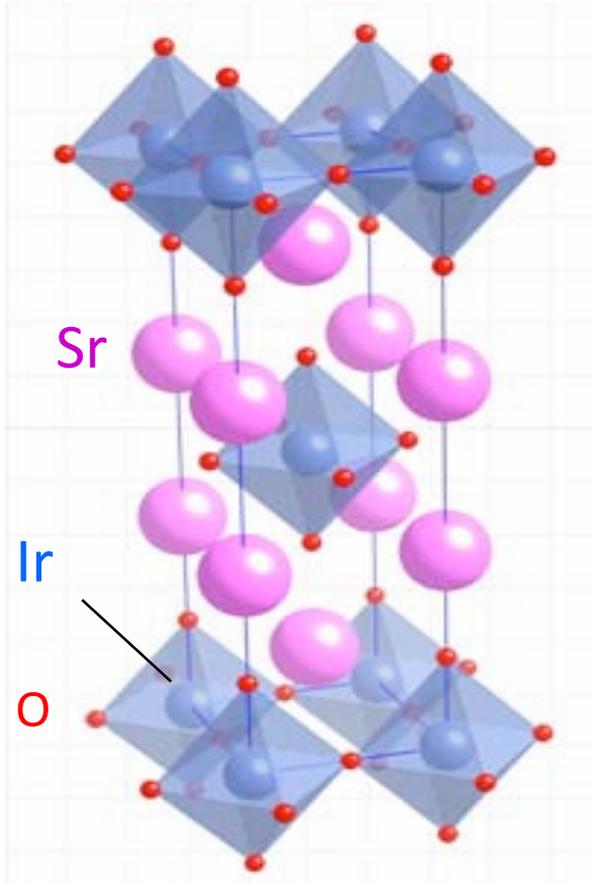

Ru : expected : hole doping
obtained : isovalent

- Substitution with transition metals
introduce charged defects
=> Role and origin of such defects ?

Why is Sr_2IrO_4 insulating ?

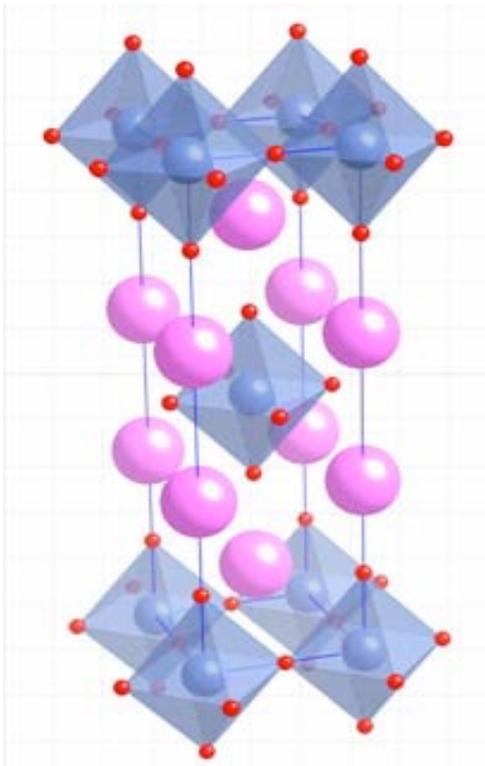

Nagai, J. Phys Soc Japan (2010)

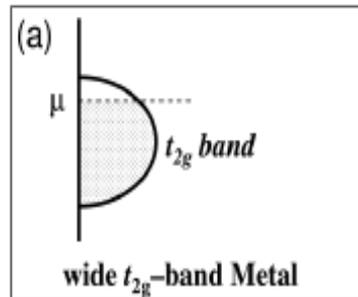

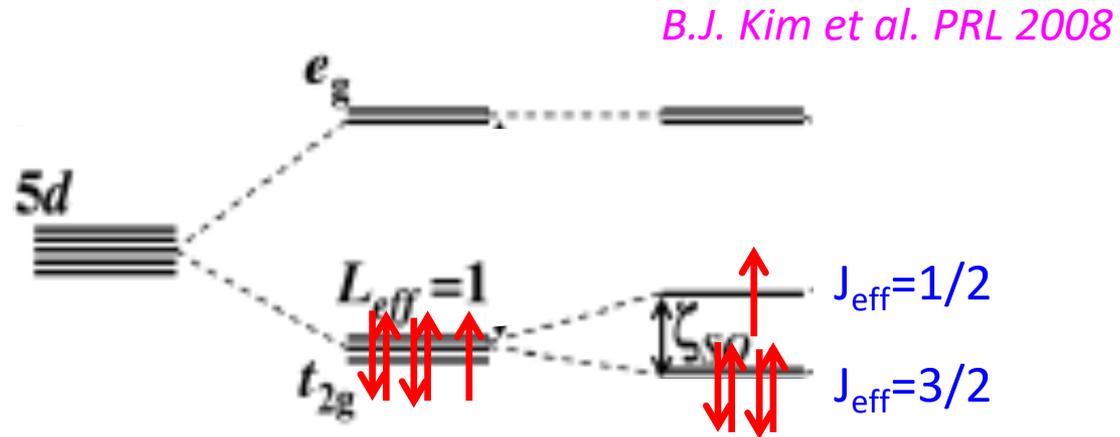

Layered perovskite : also in cuprates, manganites, ruthenates...

Sr₂IrO₄ : a spin-orbit Mott insulator

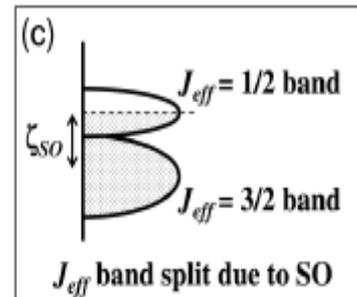

Weak correlations are expected for 5d metals. However, the strong spin-orbit splitting reshapes the band structure in a way that favors strong correlations.

Mott insulator

Anderson insulator

A. Louat, V. Brouet et al., PRB 18

Conclusions

Substitution of Ir with transition metals induce insulator to metal transition of different types

- For Rh and Ni, the metallic state is characterized by the absence of quasiparticles and a **pseudogap** on the entire Fermi Surface
- For Ru, metallicity probably develops in Ru rich domains. There is no pseudogap

Understanding how iridates react to perturbations introduced by transition metals may be important to understand iridates in general.

- Rh and Ni doping triggers the formation of local charged defects
- Ru does not transfer its hole to Ir
- ⇒ The different hybridization of these transition metals may be the key to this behavior
- ⇒ By analogy, oxygen defects may play a big role
